Purpose

A successful protocol for immediate loading of multiple implants depends on an adequate fixation and immobility of the implants in order to prevent the risk of micromovements in relation to the surrounding bone. The objective of this article was to evaluate a prosthetic concept for an accelerated rigid splinting of multiple implants for same-day immediate loading with metal-reinforced provisional restorations using a novel technique of welding temporary implant abutments with a prefabricated titanium bar directly in the oral cavity (Syncrystallization).

Materials and Methods

Between June 2004 and January 2005, immediate loading of threaded implants with a metal-reinforced, acrylic resin provisional restoration at stage one surgery was evaluated in 40 consecutive patients. A total of 192 implants were placed in selected edentulous or partially edentulous patients using the Syncrystallization technique. Once the titanium bar was welded intraorally to the abutments, opaque was applied and the provisional restoration was relined and screw-retained the same day. In addition, a comparison of deformations and stress distributions in

implant-supported, metalreinforced and non-metalreinforced resin provisional restorations were analyzed in the edentulous mandible by a three-dimensional finite element model (FEM).

Stress distributions in		
	N° Cases	N° Implants
Total Edentulous	14	103
Partially Edentulous	26	89
Total	40	192

Number of implants and cases according to partially and total edentulism

Results

All of the 192 rigidly temporized immediately loaded implants osseointegrated. An implant success rate of 100% was achieved over a period of six months post placement. No fracture or luting cement failure of the provisional restoration occurred during the observation time. Compared to mere acrylic superstructures, a

significant reduction of deformation and strain within metal-reinforced provisional restorations was detected

Discussion

Rigid temporization has been recognized to have a significant impact on the peri-implant tissue response in

immediate implant loading since it reduces the mechanical

The results of this study indicate that the Syncrystallization technique allows an expedite and adequate rigid splinting of multiple immediately loaded implants. The advantages of the new technique are:

- Reduction of treatment time for immediate temporization at stage one surgery
- Predictable fixation and immobility of implants in the early stages of bone healing
- Less time for repairing provisional restorations as a result of no or rare fracture.
